1 Introduction

This research focuses on life cycle costs and life cycle assessments of standard bridges. The life cycle analysis of standard bridges is a part of the Nordic ETSI project. The name of the project ETSI, consists of words "*Elinkaareltaan Tarkoituksenmukainen Silta*" and it could be translated "Lifelong Adapted Bridge" [1]. The bridge life cycle analysis consists of life cycle costs, life cycle assessment and bridge aesthetics. All analysed bridges belong to bridge site categorization class IV, which stands for ordinary bridges. Due to bridge site categorization class IV, bridge aesthetics is not included in this research.

The three analysed bridges were steel reinforced cantilever slab bridge, steel reinforced deck composite beam bridge and prestressed concrete beam element bridge. All the compared bridges have been chosen from standard bridge guidelines of Finnish Transport Agency. Compared bridges are typical waterway and road bridges, and the bridge deck lengths are approximately 20 meter and effective widths are 7.5 meter.

The life cycle thinking is coming increasingly important in civil and bridge engineering. The importance of life cycle assessment and overall life cycle costs are a part of "lifelong adapted bridge" thinking. Lifelong sustainable bridges are going to be adapted in bridge designing in order to obtain more cost-efficient bridges. This research was conducted as a part of Nordic ETSI project and was made by Tuomo Rantala from Finnish Transport Agency. The guidance of this research was conducted by Lic.Sc. Timo Tirkkonen and M.Sc. Minna Torkkeli from Finnish Transport Agency.

2 Etsi project [1]

ETSI project is a Nordic bridge lifetime optimisation management project, in which programs are developed to calculate bridge life cycle costs (LCC) and life cycle assessment (LCA) and to analyse bridge aesthetics. Programs developed for LCC and LCA calculations were utilized in this research.

WebLCC is a server based program to calculate bridge life cycle costs. Main parameters needed for calculations are:

- bridge investment cost
- coming maintenance and repair actions, which includes maintenance and repair periods and costs
- traffic disturbance caused by maintenance and repair, which includes maintenance and repair actions influence times, traffic disturbance costs and lengths, average daily traffic and reduction in speed limits
- Internal rate of interest.

BridgeLCA is Excel based program, which exploits also Matlab algorithm. BridgeLCA includes emissions used material and it is utilized to calculate bridge LCA and environmental impacts. In order to perform LCA calculations, are following parameters needed:

- amounts of material used in bridge construction,
- journeys to and from work, and material transportation distances and
- material consumption due to repair and maintenance actions.

3 Compared bridge type

This standard bridge life cycle analysis compares three types of Finnish standard bridges: steel reinforced cantilever slab bridge, composite beam bridge with steel reinforced concrete deck and prestressed concrete beam element bridge. Length of the superstructure is approximately 20 meter in every compared standard bridge. In cantilever bridge the bridge span is though 14 meter, which is smaller than in other two bridges.

Bridge cost estimates are calculated according Finnish Transport agency's cost estimate instructions and unit prices [2].

3.1 Steel reinforced concrete cantilever slab bridge

First analysed bridge is steel reinforced concrete cantilever slab bridge. The bridge is designed according Finnish Transport agency's "Teräsbetoninen ulokelaattasilta" standard-project drawings [3]. Single span bridge's span length is 14 meter and the length of cantilevers is 2.5 meter. Effective width of the bridge is 7.5 meter and overall width 8.3 meter. The length of the superstructure is 19 meter and the overall length of the bridge is 25 meter. End trusses and wing walls are chosen according standard-project drawings Bulc4.

Bridge waterproofing consists of double rubberized bitumen layer, under which is also epoxy waterproofing. Protective coating over the waterproofing is made from asphalt concrete AB6/50. The borders of the edge beams are also waterproofed by rubberized bitumen brushing. Between the asphalt layer and the edge beams is also installed joining compound of rubberized bitumen.

Transition slab's length is 5 meters and prepared cast-in situ. Bridge railings are standard type open railing H2 and in the middle of the bridge is also high safety net. Other bridge equipments are according standard-project drawings, such as surface water pipes, dribble pipes and charge pipes.

In the front of cone is stone rip-rap in the slope, and on the sideward of the cone and on embankment is turfing.

Bridge cost estimate is 147 000 € at earthwork cost indices of 135.9 %. Used cost indices are calculated at November 2009. Bridge cost estimate is presented at appendix 1.

3.2 Steel reinforced concrete deck composite bridge

Second analysed standard bridge is steel reinforced concrete deck composite bridge, which is designed according Finnish Transport Agency's "Teräsbetonikantinen

liittopalkkisilta II" standard-project drawings [4]. The span of the bridge is 19.45 meter and the length of the superstructure is 20 meter. Effective width of the bridge is 7.5 meter and overall width 8.3 meter. Overall length of the bridge is 27.6 meter.

Bridge superstructure consists of two steel girders and steel reinforced concrete deck, which are functioning together as composite structure. Cross beams are also used to stiffen the deck. Bridge deck is prepared cast-in-situ, and the end beams steel reinforced concrete.

Bridge waterproofing is similar, such as in cantilever slab bridge presented in chapter 3.1. Moreover, in bridge equipment belong laminated rubber bearing as well as elastic joint sealing expansion joint.

Bridge cost estimate is 159 000 € at cost indices of 135.9 %. Bridge cost estimate is presented at appendix 2.

3.3 Presressed concrete beam element bridge

The third compared standard bridge type is prestressed concrete beam elemenet bridge. The bridge is designed according Finnish Transport Agency's standard project drawings "Jännitetty elementtisilta" [5]. The span of the bridge is 19.4 meter and the total length of the superstructure is 20 meter. The effective width of the deck is 7.5 meter and the overall length is 8.3 meter.

Bridge girders consist of four prestressed concrete elements and bridge deck is castin situ. Slenderness ratio of bridge (L/H) is 20. Bridge equipments are similar as in chapter 3.2 presented composite bridge.

Bridge cost estimate is 154 000€ at cost indices of 135.9 % and it is presented at appendix 3.

4 Life Cycle costs

Analysed life cycle costs consist of bridge investment cost, maintenance and repair costs, traffic disturbance and bridge demolition cost in this report. The life cycle costs were calculated using 2 % interest rate and the chosen year of calculation is the bridge opening year. The chosen maintenance and repair actions were only the predictable actions, such as renovation of the edge beam and renewal of waterproofing.

Traffic disturbance costs are composed of the delay of the road users caused by maintenance and repair actions. The calculated traffic disturbance costs come from the decreased speed and actuating length, from where time delay is calculated for road users and multiplied by unit costs for different road users. Travel time savings for vehicle traffic is 16.09 €/h and for heavy traffic 56.02 €/h according to Finnish Road Administration guideline "Tieliikenteen ajokustannusten laskenta" [6]. Average daily traffic for all bridges is 6000 vehicle per day.

Bridge life cycle costs were calculated using WebLCC program presented in chapter 2.

4.1 Steel reinforced concrete cantilever slab bridge

Investment cost for steel reinforced concrete cantilever slab bridge consist of bridge cost estimate. The bridge cost estimate is in total 147 000 \in and per bridge square meter 780 \in /m². Price per square meter is calculated according Finnish Road Administration Bridge cost estimate using total length and effective width [2].

Maintenance actions under service life for the bridge are different cleaning actions as well as patching of the parapet and railing paintings. Bridge inspections are also calculated as bridge maintenance actions in life cycle calculations.

Repair actions under service life are composed of edge beam renovation, waterproofing renewal, repaying as well as renewal of railing and parapet. The predicted service lives for those parts are according their design ages:

- renovation of edge beam 25 years
- renewal of waterproofing 35 years
- repaving 10 years
- renewal of railing and parapet 50 years.

Bridge demolition cost is 10 % of investment cost. Overall life cycle costs are in total 239 000 € calculated to bridge opening year using 2 % interest rate. Life cycle cost per bridge square meter is thus 1270 €/ m^2 and per deck square meter 1860 €/ m^2 . Bridge life cycle costs are divided as follows

- investment cost 147 000 €
- maintenance costs 23 000 €
- repair costs 60 000 €
- traffic disturbance 7 000 €
- demolition cost 2 000 €

Steel reinforced concrete cantilever slab bridge LCC distribution

Bridge life cycle distribution is presented in figure 1.

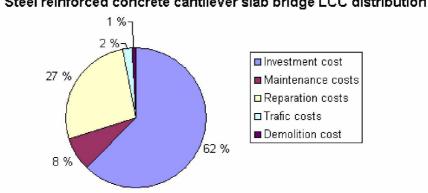

Figure 1. LCC distribution of steel reinforced concrete cantilever slab bridge.

4.2 Steel reinforced concrete deck composite bridge

Investment cost for steel reinforced concrete deck composite bridge 159 000 € according to cost estimate. Price per bridge square meter is 770 €/m².

Maintenance actions are likewise the same as for steel reinforced concrete cantilever slab bridge presented in chapter 4.1. Moreover, for composite bridge repair actions belong repainting of steel beams as well as maintenance and cleaning of expansion joints and bearings.

Repair actions under bridge service life are furthermore likewise as in steel reinforced concrete cantilever slab bridge. The similar repair actions are renovation of edge beam, renewal of waterproofing, repaying as well as renewal of railing and parapet. In addition, to composite bridge repair actions belong renewal of expansion joint and bearing every 35 years under major overhaul.

Bridge demolition cost is 10 % of investment cost. Overall life cycle cost for composite bridge are in total 305 000 € calculated to bridge opening year using 2 % interest rate. Cost per bridge square meter accrue thus 1470 €/m² and per deck square meter 2030 €/m². Bridge life cycle costs are divided as follows

- investment cost 158 000 €
- maintenance costs 62000 €
- repair costs 72 000 €
- traffic disturbance 10 000 €
- demolition cost 2 000 €

Bridge life cycle cost distribution is presented in figure 2.

Steel reinforced concrete deck composite bridge

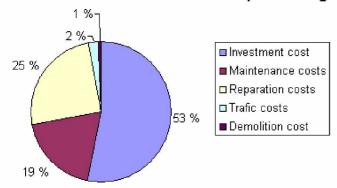

Figure 2. LCC distribution of steel reinforced concrete composite bridge.

4.3 Presressed concrete beam element bridge

The investment cost of the prestressed concrete beam element bridge is 145 000 € according to cost estimate. Price per bridge square meter is 690 €/ m^2 . Demolition cost of the bridge is 10 % of the investment cost. Maintenance and repair actions of the element bridge are likewise the same as for steel reinforced concrete deck composite bridge excluding the repainting of steel girders.

Overall life cycle costs of the prestressed concrete beam element bridge is in total 284 000 €. Price per bridge square meter accrue thus 1 270 €/m² and per deck square meter 1 890 €/m². Bridge life cycle costs are divided as follows

- investment cost 154 000 €
- maintenance costs 45000 €
- repair costs 75 000 €
- traffic disturbance 8 000 €
- demolition cost 2 000 €

Bridge life cycle cost distribution is presented in figure 3.

Prestressed concrete beam element bridge LCC distribution

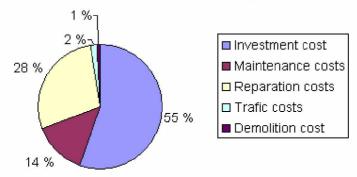

Figure 3. LCC distribution of prestressed concrete beam element bridge.

5 Bridge life cycle assessment

Life cycle assessment for standard bridges was performed by calculating material amounts used for bridge parts as well as for construction, maintenance and repair. Used material amounts are multiplied with emission loads in order to obtain environmental impacts. Transportation of workers and goods was ignored in life cycle assessment due to challenging evaluation. Moreover, the total transportation emissions would be closely-spaced thus making comparison of the materials more sensible.

Environmental impacts were determined using the BridgeLCA program presented in chapter 2. Amounts of environmental impacts were evaluated using measured emissions of Western Europe at 1995. [1]

Environmental impacts are categorised in six factors:

- Abiotic depletion, equivalent emission Antimony Sb,
- Acidification. equivalent emission sulphur dioxide So₂
- Eutrophication, equivalent emission phosphate PO₄
- Global warming potential, equivalent emission CO₂
- Ozone layer depletion., equivalent emission Trichlorofluoromethane CFC-11
- Photochemical ozone layer creation, equivalent emission ethylene C₂H₄.

Combined effect of the environmental impacts was calculated using weighting of emissions according to United States Environmental Protection Agency's factors. Weighting factors are presented in table 1.

Table 1. Weighting factors of environmental impacts according to US-EPA [1].

| | ADP | AP | EP | GWP | ODP | POCP |
|-------------------|-----|----|----|-----|-----|------|
| Weighting factors | 5 | 5 | 5 | 16 | 5 | 6 |

The weighted comparison between standard bridges is presented in table 2. In comparison, the environmental impact of the steel reinforced concrete deck composite bridge is largest and steel reinforced concrete cantilever bridge's is lowest. Figure 4 present the weighted accumulation of environmental impact of standard bridges.

Table 2. Environmental impact comparison.

| Weighted environmental impact, comparison value for effects | | Per deck square meter [-] |
|---|---------|---------------------------|
| Steel reinforced concrete cantilever slab bridge | 2257514 | 15842 |
| Steel reinforced concrete deck composite bridge | 2677532 | 17850 |
| Prestressed concrete beam element bridge | 2566149 | 17108 |

6 Conclusions

6.1 Life cycle costs

In bridge life cycle cost comparison, overall cost and price per bridge deck square meter were compared. The overall cost of steel reinforced concrete cantilever slab bridge is 239 000 € and price per deck square meter is 1680 €/m². The overall cost of steel reinforced concrete deck composite bridge is 305 000 € and price per deck square meter is 2030 €/m². The overall cost of prestressed concrete beam element bridge is 284 000 € and price per bridge square meter is 1890 €/m². Table 9 represents the life cycle cost comparison of standard bridges.

Table 9. The life cycle costs of standard bridges.

| Life cycle costs [€] | Total cost | Per deck square meter |
|--|---------------|--------------------------|
| Steel reinforced concrete cantilever slab bridge | 236 000 | 1660 |
| Steel reinforced concrete deck composite bridge | 299 000 | 1990 |
| Prestressed concrete beam element bridge | 279 000 | 1860 |

The most inexpensive bridge is of steel reinforced concrete cantilever slab bridge, the second inexpensive bridge is prestressed concrete beam element bridges and the most expensive bridge of compared standard types is steel reinforced concrete deck composite bridge. Although, the span length of steel reinforced concrete cantilever slab bridge is shorter than in other two compared bridge. Therefore, the overall cost is also lower.

The calculated prices for bridge deck square meter are not directly comparable for bridges with different length and width. For longer bridge length, the steel reinforced concrete cantilever slab bridge would not have such vantage. Moreover, concrete deck steel beam composite bridge would be more economical in longer span lengths. In addition, multi-span bridges were not taken into account in bridge life cycle costs. In bridge life cycle cost comparison, all possible maintenance and repair actions were not taken into account. On the contrary, predictable and notable actions were taken into account.

Bridge demolition costs were estimated to be 10 % of bridge overall costs. The estimate is not precise for every compared standard bridge types. However, due to discounted values, the effect of demolition cost is minor thus making the margin of error insignificant.

6.2 Life cycle impacts

The compared standard bridges are almost the same lengthy and their purpose of use is same. Therefore, these standard bridges are suitable for life cycle assessment. Although, the steel reinforced concrete cantilever slab bridge is one meter shorter

than other two bridges, which benefit the comparison for that. Table 10 represents the environmental impacts per deck square meter.

Table 10. Environmental impacts of standard bridges per deck square meter.

| Environmental impact per | ADP | AP | EP | GWP | ODP | POCP |
|--------------------------|------------|-----------------------|-----------------------|-----------------------|--------------|-------------------------------------|
| bridge deck square meter | kg Sb eq | kg SO ₂ eq | kg PO ₄ eq | kg CO ₂ eq | kg CFC-11 eq | kg C ₂ H ₄ eq |
| Cantilever slab bridge | 10,4911825 | 3,82461657 | 0,634881 | 985,3842 | 0,000208292 | 0,2172116 |
| Composite bridge | 11,8837254 | 4,13467772 | 0,659116 | 1110,316 | 0,000215794 | 0,2932564 |
| Prestressed bridge | 11,2500244 | 3,9769304 | 0,595538 | 1064,193 | 0,000213165 | 0,2423228 |

In comparison, the steel reinforced concrete cantilever slab bridge prove to be most environmentally friendly bridge, the next is prestressed concrete beam element bridge and the least environmentally friendly is steel reinforced concrete deck composite bridge. Because all of the compared bridges are small, are the environmental impacts respectively small thus making the LCA comparison for bridges insignificant. However, for multiple bridges, the LCA comparison could be sensible.

In LCA comparison, it is need to taken into account, that the span length of steel reinforced concrete cantilever slab bridge is just 14 meter, where for other two standard bridge the span length is longer. That is why the cantilever bridge has benefit against two other compared bridges. However, the lengths of the decks are nearly the same, for which makes the comparison suitable.

The values of environmental impacts are not significant for small standard bridges with current emission costs. The used estimation value per carbon dioxide is 20 €/ton. The calculated values for standard bridges are

- 2 800 € for steel reinforced concrete cantilever slab bridge
- 3 400 € for steel reinforced concrete deck composite bridge
- 3 200 € for prestressed concrete beam element bridge.

Margin of cost between first and second alternative is only $600 \in$. As a conclusion, calculated emission costs are insignificant for smaller bridges with current emission costs. However, the importance of environmental impacts could be significant with weighting for environmental impact values.

7 Summary

Life cycle optimisation for standard bridges is a method to optimise the economical and environmentally friendly solution for choosing the best bridge type alternative. When optimising the bridge types, the esthetical value of bridges should not be ignored.

Life cycle analyse consisted of comparing three standard bridges: steel reinforced concrete cantilever slab bridge, concrete deck composite bridge and prestressed concrete beam element bridge. The most economical solution of compared bridges proved to be steel reinforced concrete cantilever slab bridge and the second economical is prestressed concrete beam element bridge. The concrete deck composite bridge proved to be most expensive.

The most environmentally friendly bridge proved to be steel reinforced concrete cantilever slab bridge, and the second environmentally friendly bridge is prestressed concrete beam element bridge. The least environmentally solution is concrete deck composite bridge.
