Finnish survey on relative income differences

ISBN 951-46-1952-8

Helsinki 1976. Valtion painatuskeskus

Preface

This study of relative income differences within the population is part of a survey carried out separately by the following seven countries: Canada, Finland, France, Hungary, Poland, Spain and Sweden under the auspices of the Statistical Commission of the United Nations.

The goals and methods of the study are explained in document Conf. Eur. Stat./WG 22/29. The study of Finland has been carried out by the Central Statistical Office as part of the 1971 household budget survey. The study was supervised by Jorma Linnaila.

 - 5.3.1. Wages and salaries
 - 5.3.2. Entrepreneurial income
 - 5.3.3. Property income
 - 5.3.4. Transfers paid and received
 - 5.3.5. Social benefits in kind
 - 5.4. Other classifications
 - 5.4.1. Socio-economic classification
 - 5.4.2. Size of household
6. Reliability of data
 - 6.1. Sampling and non-sampling errors
 - 6.2. Comparison with macro-data
 - 6.3. Total variances

TABLES

1. Background

The Finnish contribution to the international comparison of relative income differences within the population is based on the 1971 household budget survey. The frame of the household budget surveys carried out every five years is based on a comparatively large consumption study. The basic data on consumption expenditure are collected partly by means of monthly book-keeping and partly by means of yearly interviews. The data on the structure of households and the basic data on the incomes and the use of public services by households, used in this report, were also collected in connection with the interviews for the 1971 survey. The interviewing method was closely connected with the use of external registers. For example, the main part of the income items needed for the calculation of the disposable income of the sample households were obtained from taxation data. Likewise the items of income transfers based on the national basic pension scheme were obtained directly from the National Pensions Institution.

2. Sample design

The population of the study consisted of persons who during the year 1971 had lived in private households. Persons in institutional households, e.g. homes for the aged, children's homes, hospitals and penal institutions have not been included in the population, nor private persons who have died during the year or such households of which all members have emigrated.

The sample was selected from the central register of population as a one-stage sample of housing units, thus households nearly from all the communes of the country were represented in the sample. The use of the housing unit as the sampling unit is due to the fact that there is no household code in the register of population. At the Central Statistical Office (CSO) the housing units included in the sample were distributed into households on the basis of the name etc. data. All the separate households living in the same dwelling were included in the sample. The final checking of the composition of the households was done in connection with the interview.

The sample of the income inquiry consisted of two partial samples, one selected for the monthly book-keeping the other for the annual interview. The basic sample of the monthly book-keeping was stratified so as to include all agricultural households. Of other households only every other was included.

The size of the sample for the yearly interviews was 11 300 households of which 8 817 households were included in the final data. An attempt was made to remove structural differences in the population and sample, resulting from varying sampling fractions and non-response, by means of raising factors. The raising factor given to each household indicates how many households of the population the sample household corresponds to. The sum of raising factors denotes the number of households in the population or in the part of the population under observation. In these structural checkings attention was paid to the regional distribution and socio-economic classification of the sample. In addition, the under-representation of one-person households was corrected to correspond to the population. The data on the population were obtained from the 1970 population census.

3. Data collection

As mentioned above, the basic data were collected partly by means of interviews partly by using administrative registers. The data on the structure and background of households were collected by means of interviews as well as the data on such income items that could not be obtained from other sources or had been defined in the register data in the way which deviates from the statistics of income distribution. The most important income items obtained by the interviewing method were the following:

- the imputed rental value of owner-occupied dwellings
- the value of own work done for the new construction, extension or repairs of dwellings, whether owner-occupied or rented
- income from rented dwellings
- the value of home-produced agricultural products and services in household consumption
- the net amount of interests and dividends.

Of the income transfers received, i.e. the data on income transfers and social assistance based on the equalization system of family expenses were collected by interviewing.

The data on wages and salaries, direct taxes and also the main part of entrepreneurial income were obtained by mail inquiry to tax offices.

The data on income transfers based on the national basic pension scheme, and health insurance compensations and allowances received by the sample households were transferred in computer form from the data base of the National Pensions Institution.

Before the interviews a personal letter to the heads of the households was sent. The letter explained the purpose and execution of the survey and stressed the confidentiality of the data. An attempt was made to perform the interviews so that besides the family head all other members of the household who had received income during the year were present.

4. Data handling

The coding of income data and the automatic data processing were performed at the CSO. The checking of the basic data was done in the following order:

- (a) first was checked that the coding of each column was done according to the instructions given
- (b) the upper and lower limits of income items were checked
- (c) the internal logic of card types was checked (comparison of columns)
- (d) the logic between card types was checked
- (e) checkings between the data of the monthly book-keeping and yearly interviews were done.

5. Definitions and classifications

The concepts and classifications used in the enclosed tables are based as far as possible on the recommendations given for the international comparison of income differences. However, some exceptions from these recommendations have been necessary due to the collection method and structure of the basic data.

5.1. Household

The survey covered in principle all persons who during the year 1971 had belonged to the households in the sample. The membership of the household was determined on the basis of the criterions: persons living together and having wholly or partly common household arrangements. Additionally attention was paid to the fact that the definition of the household limits was sensible from the viewpoint of income source.

5.2. Earners and regular full-time earners

In accordance with the recommendations, earners are defined as persons who have had earnings in 1971 irrespective of the amount of work performed or the size of earnings. Further, unpaid family members are also included in this group.

The definition of regular full-time earners differs from the recommendations. Following the definition used in the household surveys in Finland, this group includes all earners who performed an earning activity during 330 days in 1971 (including paid holidays and sick-leave). Part-time workers etc. have been excluded.

Entrepreneurial income from agriculture and forestry was divided among gainfully employed household members over 18 years of age in ratio to their working time. The estimates were based on household survey data on yearly working days completed and the length of an average working day.

5.3. Income

5.3.1. Wages and salaries

The definition corresponds to the recommendations. Thus for instance employers' contributions to social security schemes and private pension funds are not included in wages and salaries. Pensions received directly from the employer have been treated as income transfers.

5.3.2. Entrepreneurial income

Entrepreneurial income consists of the net income from non-corporate enterprises and transfers made by owners from the income of corporate enterprises. The income was mainly obtained from the taxation material which in the case of entrepreneurial income from agriculture also is based on book-keeping. Property income received by enterprises, such as interests, income from rent and fees for right of disposal, have not been separated from entrepreneurial income. Entrepreneurial income has been calculated at its net sum by subtracting depreciations.

Entrepreneurial income from agriculture and forestry was worked out partly by means of interviews, partly by the aid of data on taxation. The consumption of own products by farmer households has been valued at the price the producer normally gets when he sells a product.

Entrepreneurial income also comprises the net rents of owner-occupied dwellings, which have been treated in accordance with the SNA. Net rents were calculated as the difference between the rental value and cost items (incl. depreciations). When defining the rental value, the objective was the current rent which could be had from a similar dwelling in each place.

5.3.3. Property income

Property income include the net amount of interests, dividends, land rents and royalties. Property income data, together with data on savings, have proved to be the most complicated items to work out of the Finnish household surveys and the results show a clear downward bias.

5.3.4. Transfers paid and received

Transfers received by households comprise transfers from governmental bodies, private non-profit institutions, enterprises, and other households. Transfers paid by households have been worked out in an analogous way. Insurance benefits received on the basis of private insurance have also been treated as transfers. The group other current

transfers also includes items of capital transfer type.

5.3.5. Social benefits in kind

In the 1971 household survey attempts were made to work out the value of social benefits in kind received by households. Similar attempts have not been made in earlier household surveys in Finland. In accordance with the recommendations for the international income survey, educational services, medical and other health services, welfare services, housing subsidies, recreational and related cultural services were included in the survey plan.

In the survey such services have been treated, the utilization of which can be specified by individual or household. The aim has been to eliminate administrative costs and research costs when determining the value of the benefits.

The method of calculation is partly based on interview data on the utilization of the services in question and the costs they cause to users, partly on external statistical data etc. on the values per unit of various services and in some cases on subsidies received from public authorities for the production of the services. The free-of-charge social benefits in kind are the current expenditures reduced by the payments of households and the compensations for instance from health insurance. In the case of recreational and related cultural services, the social benefits are the subsidies received from the public authorities for the activity in question, calculated per time attended etc.

The estimate of the most important free services was made as follows:

Interview data on the utilization of educational services concerned the time of studying at various institutes, as well as times attended in the case of some institutes related to adult education. Corresponding cost data per student or time attended were obtained partly from official statistics, partly from education authorities and other related sources. The free services received by students living in free boarding-houses were estimated by means of data in the length of stay and the official rent statistics.

Data on free school transport were collected by means of interviews about the number and length of trips. The prices for serial tickets for trips of equal length were used as price data. Data on study loans were collected by means of interviews about the loan interest and the amounts paid in interest. When calculating the social benefit, 8 % was used as the average current rate of interest.

The group medical and other health services contained social benefits received from hospitals, outpatient departments, and doctors, further from maternity and children's advisory centres, mental care centres and tuberculosis centres and school health care. The interview data either concerned days of treatment or number of times attended. Data on costs per unit were obtained from the statistics compiled by the hospital association or directly from the authorities concerned.

Welfare services comprise day care of children, juvenile reformatories and children's summer holiday camps. Data on days in care were collected by means of interviews and corresponding data on costs were estimated on the basis of data provided by the social authorities.

Housing services. As the value of the subsidy received was regarded the interest benefit produced by a housing loan with lower than normal interest compared to interest rate of normal bank loans. Whether a rented dwelling was concerned for which the board of housing had provided a loan the value of housing subsidy is the normal rent reduced by the rent paid by the household.

As for recreational and related cultural services, the survey was restricted to theatre, library and some sports services. Data on the utilization of services were collected during interviews in a relatively rough form. Cost data on the number of times attended and books taken out were obtained from the authorities in question.

5.4. Other classifications

5.4.1. Socio-economic classification

The socio-economic classification is based on data on employment status and occupation. The household survey made use of the classification of occupations in the 1970 population census, which is based on the Nordic classification of occupations of 1963 and the International Standard Classification of Occupations published by the International Labour Office in 1958. The distribution of workers into skilled and unskilled workers was performed on the basis of occupational data in the same way as in the 1970 population census.

5.4.2. Size of households

The enclosed tables follow the classification used in the Finnish reports of the survey in which households composed of five and six or more persons have been separated. The subdivisions according to the number of grown-ups and children in households composed of four, five and six or more persons have been made taking into account the size of the groups in the sample material.

6. Reliability of data

6.1. Sampling and non-sampling errors

The income data of the household survey are subject to errors of various kinds. Besides random errors, the results are affected by non-response during the interviewing phase, the forgetfulness and negative attitudes of the interviewed etc. Corresponding biased estimates are also obtained for some income items from taxation material.

The variance of the mean income was calculated according to the detailed socio-economic classification for the same income concepts for which total variances were output, see subsection 6.3.

Mean errors over 5.0 % were obtained for the following groups.

Yearly earnings (all earners and regular full-time earners)

- (1) employers
- (2) own-account workers in professional, technical, consulting and similar fields

Distributed factor income per household

- (1) employers
- (2) own-account workers in professional, technical, consulting and similar fields
- (3) manual workers employed in agriculture

Available income per household

- (1) employers
- (2) own-account workers in professional, technical, consulting and similar fields

Mean data for all groups irrespective of the amount of material have been presented in the enclosed tables. On the basis of the experiences received from the random errors of the 1971 household survey, the means both by household and by individual are, however, quite unreliable for the groups the size of which is under 40 (proportional share from the material under 0,5 %).

6.2. Comparison with macro-data

The comparison of the household survey results with other statistics is hampered by the lack of reliable and conceptually corresponding data. In the first place the data of national accounts statistics can be brought into question. Because of conceptual differences even this comparison remains rough.

According to the 1971 national accounts statistics the disposable incomes of households and private nonprofit institutions were 29 121 million marks. The corresponding estimate without nonprofit institutions obtained from the household survey was 15 % smaller, i.e. 24 714 million marks. In the following the figures of the household survey and national accounts statistics have been compared for those parts where the income concepts can be considered to be roughly of the same contents.

	Household survey † %
	of the figures of the national accounts statistics
Wages and salaries	- 0.9
Incomes of private entrepreneurs	
Agriculture and forestry	- 19.3
Other entrepreneurship	- 18.6
Income transfers received from the public sector	- 0.8

Even the accurate comparison of the estimates of social benefits in kind is difficult because of the difference in statistical base. On the basis of the observations made it however seems that the correspondence for educational services is relatively good. Estimates concerning health services seem to remain somewhat too small due to the fact that the participation of the sick and old people in the household survey is more difficult than that of other population groups. On the other hand the estimate of welfare services per household is clearly higher in the household survey than in the statistics of social expenditure. This may be explained by the fact that the expenditure of congregations and private institutions are not included in macro-statistics. Results concerning housing services remain somewhat smaller than the estimates obtained from the statistics of social expenditure. The interviewing data may have remained deficient for housing because of their delicate nature.

6.3. Total variances

Estimates of total variances which were supposed to be calculated in the report on the second consultation of the countries participating in the international comparison of relative income differences are found below.

Households	Total variances
Distributed factor income per household	287 127 000 (FMK)
Available income per household	138 326 000 (FMK)
Available income per capita	17 457 000 (FMK)

Individuals

Yearly earnings of all earners	115 666 000	(FMK)
Yearly earnings of regular full-time earners	122 970 000	(FMK)
