In Aud. Phil. die 20 Septembris 1815:

h. a. m. c.

ABOÆ, Typis FRENCKELLIANIS.

Complurimum abque Celeberrimo D^{no} Professore, Co-
mis Philosophorum ad elucidanda haec attendunt
canone Maxime spectabilis fautor ac summatissime

Auctori hujusce dissertationis Clarissimo
rem gerere cupiens partem, quas ei placuit mihi in-
gere, suscipere amicitia ejus majorem habens ratio-
nem, quam vel studiorum meorum a materia jam
ventilanda ~~longe~~ diversarum distantiarumque, vel ne-
diorum, quae me quidem distabant tenentia ad hanc ac-
circingi haud potuerunt. Consistens itaque mihi in offi-
ciosa ^{per} captura mihi Tu Amplissime Vir cui huc
probatione praesides, ne deneges aures faciles, facere
que anaximae affirmantem, omnino qua deest verborum
roga honore.

Ad Te, Clarissime Vir Candidate non longe
hi est praeternites. ^{opus} tanta enim est animi tui serice
in amicitia colenda quanta in artibus doctrinisque
et in primis in sublimi illa astronomia frequentia pro-
cedis mentis acies et perspicacia. Cum igitur is non
documentes probaturus ^{is} quem dignus ^{est} ^{visendi} quod te ja-
spectat trabes, ^{quis} faceret ~~amiculis~~ ~~meum~~ vel studio
meorum diversitate, vel temporis angustia tibi eas si-
praemeditata, quas forte allelatus sum, circa dejectionem de
laudatam approbatione, minores comitanda minaque solide invenire

Inter diversa phænomenorum cælestium genera ad inveniend^{as} meridianorum differentias primum occupant occultationes stellarum a Luna, haudque infimum eclipses etiam Solis ab hac vel planetis inferioribus locum, quorum calculo inservientes formulas plurimi præstantissimi Viri, LAGRANGE, LEXELL, DUSEJOUR, BOHNENBERGER, DELAMBRE, OLBERS & LITTROW a) publici juris fecerunt. Plurimæ harum facile ab aliis possunt derivari, neque tamen omnes pratico respectu ejusdem sunt commoditatis. Inter has diversas methodos, ut quidem mihi videtur, brevissime forsitan usurpatur vel ea quæ a BOHNENBERGER (Geogr. Ortsbest. pagg. 339 & 345) ope nonagesimi traditur, vel præstantissima illa ab OLBERS (Astron. Jahrb. 1811) proposita. Etsi vero OLBERS & LITTROW methodos etiam tradiderunt calculum parallacticum tam respectu Ascensionis rectæ & Declinationis, quam altitudinis & azimuth peragendi, elegantiore tamen hæ formulæ analyticam formam, quam commodiorem practicum habent| usum. Sunt enim Loca Lunæ respectu ecliptices in tabulis data, & motus ejus ad æquatorem

A torem

a) Neque silentio prætereundæ sunt formulæ Clar. BESSEL, quibus datis veris Lunæ ad eclipticam relatis positionibus, apparentes Ascensiones Rectæ & Declinationes mox computantur. Hæc methodus calculandis e tabulis occultationibus fixarum maxime est idonea,

torem relatus magis inæqualis est quam ad eclipticam. Porro, si eclipses stellarum vel Solis ad horizontem computantur, major requiritur labor, cum loca, quæ in tabulis ad Eclipticam referuntur, primo ad æquatorem, mox ad horizontem reduci debeant. Quid? quod in computandis ad usus geographicos phænomenis his, hæc ultima methodus minime est idonea, & usus hujus tantum ad eos casus restringitur, ubi e tabulis tantum & elementis e theoria datis calculantur eclipses. In usum eorum, qui forsitan unam alteramve harum formularum, BORNENBERGERII sc. & OLBERSII non viderunt, eas hic afferam. Designent L, λ, D , Longitudinem, Latitudinem & Radium Lunæ (vel Solis^e) veram, L', λ', D' , easdem apparentes, β Latitudinem loci geocentricam, ε Eclipticæ obliquitatem, α Tempus sidereum (cum Nut. in A. R.), p Parallaxem Longitudinis, π parallaxem horizontalem æquatorem, ϱ radium terræ ad æquatorem relatum, & erit secundum BORNENBERGER:

$$\begin{aligned}
 \sin b &= \sin \beta \cos \varepsilon - \cos \beta \sin \varepsilon \sin \alpha \\
 \sin N &= (\sin \beta \sin \varepsilon + \cos \beta \cos \varepsilon \sin \alpha) \sec \beta \\
 \operatorname{Tg} p &= \frac{\varrho \sin \pi \cos b \sin (L - N)}{\cos \lambda - \varrho \sin \pi \cos b \cos (L - N)} \\
 \operatorname{Tg} \lambda' &= \frac{(\sin \lambda - \varrho \sin \pi \sin b) \cos p}{\cos \lambda - \varrho \sin \pi \cos b \cos (L - N)} \\
 \sin D' &= \frac{\cos p \cos \lambda' \sin D}{\cos \lambda - \varrho \sin \pi \cos b \cos (L - N)}
 \end{aligned}$$

For

^e) Parallaxis Longitudinis Solis & Lat. app. ope priorum calculentur formularum, quæ tum insignem abbreviationem admittunt. Pro Sole & planetis est $D' = D$.

Formulæ Olbersianæ hæc b) sunt

$$\text{Tang } L' = \frac{\text{Sin } L \text{ Cos } \lambda - \varrho \text{ Sin } \pi (\text{Sin } \alpha \text{ Cos } \beta \text{ Cos } \varepsilon - \text{Sin } \beta \text{ Sin } \varepsilon)}{\text{Cos } L \text{ Cos } \lambda - \varrho \text{ Sin } \pi \text{ Cos } \alpha \text{ Cos } \beta}$$

$$\text{Tg } \lambda' = \frac{[\text{Sin } \lambda - \varrho \text{ Sin } \pi (\text{Sin } \beta \text{ Cos } \varepsilon - \text{Sin } \alpha \text{ Cos } \beta \text{ Sin } \varepsilon)] \text{ Cos } L'}{\text{Cos } L \text{ Cos } \lambda - \varrho \text{ Sin } \pi \text{ Cos } \alpha \text{ Cos } \beta}$$

$$\text{Sin } D' = \frac{\text{Sin } D \cdot \text{Cos } L' \text{ Cos } \lambda'}{\text{Cos } L \text{ Cos } \lambda - \varrho \text{ Sin } \pi \text{ Cos } \alpha \text{ Cos } \beta}$$

Labor calculandi eclipses in his duabus methodis fere idem est, id vero commodum non negligendum, quod Bohnenbergianæ tantum cum quinque vel sex ad summum figuris decimalibus logarithmorum computentur, quod etiam valet de partibus posterioribus duarum primarum OLBERSII & tota tertia formula, ubi præterea, prima, cum apparens tantum longitudo detur, summa cura e tabulis trigonometricis supputetur. Perspicuum est, in utraque methodo (si Nonagesimus per allatas formulas computatur) calculum breviorē reddi, si quantitates constantes Sin β Cos ε , Sin β Sin ε , Log Cos β Cos ε , Log Cos β Sin ε & ϱ seu etiam Log (1 — ϱ) pro diversis locis e tabula depromi possint, quare igitur non inutile duxi, has pro quibusdam speculis astronomicis, & locis aliquot borealibus, quorum Longitudines ex observatis occultationibus computare forsā si fata tulerint, in animo est, hæc sistere & in communem usum promulgare.

Necesse est, ut maxime probabilis in hoc calculo assumatur valor ellipticitatis telluris. Hic diversis modis, secum in-

A 2

vicem

b) *Astr. Jahrb.* 1811, Quæ in *Astr. J. B.* 1808 occurrunt, forsā non tam commodæ sunt, saltem eam abbreviationem calculi non admittunt.

wicem bene consentientibus prope $\frac{1}{303}$ constituitur. Verissimum est, graduum mensuras multum a se invicem abluere, verumque ita est, paucis m. secundis in Latitudinibus extremorum arcus mensurati punctorum mutatis, vel etiam variatis quam minime longitudinibus basium (quæ sæpe admodum breves fuerunt), omnes ad eandem posse ellipticitatem reduci. Combinatio vero omnium, (quæ vero plurimæ non ita sunt accuratæ, ut certitudinem 1" in Latitudinibus, cum adhuc major præcisio ad hunc usum necessaria esset, habeant), CLO LINDENAU dedit $\frac{1}{304}$ c); mensuraque gallica novissima duce DELAMBRE & MECHAIN cum suecana a SVANBERG peracta comparata, quæ ambæ sine dubio accuratissimæ sunt $\frac{1}{307,1}$ d); Duæ æquationes Lunares, quod notum est, una in Longitudine, altera in Latitudine, quarum coëfficientes a BURG empirice sunt determinatæ, $\frac{1}{307}$; & ex 29 selectis pendulorum observationibus ab HALLSTRÖM e) ad calorem 0° & spatium aëre vacuum correctis formula pro longitudine penduli sexagesimalis per methodum minorum quadratorum sequitur $439,230 + 2,343 \sin \beta'^2$ lin. paris., quæ ellipticitatem requirit $\frac{1}{304}$. Præterea novissima gallica mensura ad finem perducta bene cum valore $\frac{1}{307}$ consentit, cum longitudo arcus meridiani inter Formenteram & Dunkerque ex observationibus tantum 0,41 metris diversa ab ea, quam dicta hæc ellipticitas poscit, inventa sit f).

In sequentibus igitur assumsi valorem $\frac{1}{303}$, quo posito, Latitudo apparens & vera sint β' & β , quo habeatur $Tg \beta = \left(\frac{c}{303}\right)^2$

c) v. ZACH *Mon. Correspondenz* 1806, Aug.

d) SVANBERG *Mesure d'un arc du Meridien*, Préf. pag. XXVIII.

e) Dissert. de Fig. Tell. ope Pendul. determinanda P. III. pagg. 9, 10. P. V. pagg. 3. 4.

f) BODE *Astron. Jahrb.* 1813. pag. 252.

$(\frac{304}{100})^2$ Tang β' , & logarithmus hujus coefficientis (Logarithmis fractionum propriarum semper denario auctis) = 9,9971476, vel etiam

$\beta' - \beta = 677''$, $4 \sin 2 \beta' - 1''$, $1 \sin 4 \beta'$, ubi Log. Coeff.

sunt 2,83085 & 0,046. Ad calculandum ϱ sequentes inseruiunt formulæ, approximatiuæ quidem, sed eandem præbentes præcisionem, quam formulæ rigorosæ ope usitatarum tabularum trigonometricarum:

$$\varrho = 1 - 0,00325189 \sin \beta'^2 - 0,00002658 \sin \beta'^4$$

(Log. 7,512135; 5,4245).

$$\text{Log } \varrho = 10 - 0,00141228 \sin \beta'^2 - 0,00001384 \sin \beta'^4$$

(L. 7,149920; 5,1408).

$$\text{Log } (1 - \varrho) = \text{Log } \sin \beta'^2 + 7,512135 + p \sin \beta'^2 - q \sin \beta'^4.$$

Log $p = 7,5502$; Log $q = 5,463$.

Hæc ultima formula, reliquarum commodissima, ea est, cum qua tabellam construxi. Est vero, si $\pi = \text{par. æqu.}$, $\pi' = \text{loci}$, accurate $\sin \pi' = \varrho \sin \pi$, non vero exacte $\pi - \pi' = (1 - \varrho) \pi$, error vero, qui ordinis quinti est, in nullo casu ultra $0''$,01 ascendit.

Exhibet igitur sequens tabella valores antea nominatos, adjunctis eorum variationibus pro diff. $10''$ in ε & β , ejus quidem variatio insensibiliter differt a variatione τ & β' si hæc $30''$ seu $40''$ minor g), præsertim si hæc omnia ad sex figuras decim. logarithmicas computentur, quod abunde sufficit, cum variatio

Log

g) Probat hoc formula approximatiua: $\Delta (\beta' - \beta) = 0''$,00657
 $\cos 2 \beta' d \beta' - 0''$,00005 $\cos 4 \beta' d \beta'$, ubi $d \beta$ in secundis exprimitur.

Log. Sin π etiam pro $\pi = 62'$ & pro $0'',01$ unitatem in sexta figura excedat. Et si parallaxis Lunæ tantum ad $0'',1$ datur, quinque sufficiunt figuræ. Cum omnes novissimas astronomicas Latitudinum determinaciones præsertim in v. Zach M. Corr. adhuc videre mihi non licuerit, plurimas e tabulis Gothanis (1804) Solis, & recentioribus quibusdam datis assumi.

Explic. Exhibet pro quovis loco prima & secunda linea latitudinem apparentem & veram, tertia Log Cos β Sin ε (ε vero 23° 28' assumpta), adjecta variatione pro $\Delta \beta = 10''$, quæ negativa est, ubi constans variatio pro $\Delta \varepsilon = 10'' = \frac{1}{4} 485$; quarta, Sin β Cos ε , subjunctis variationibus in eadem linea

B

pro

pro $\Delta \beta = 10''$ & in posteriori pro $\Delta \varepsilon$, quæ negativa; quinta $\text{Log Cos } \beta \text{ Cos } \varepsilon$, cujus variatio pro $\Delta \beta$ eadem est ac in linea tertia, & ubi pro $\Delta \varepsilon = 10''$ constans variatio = $-91,4$; sexta $\text{Sin } \beta \text{ Sin } \varepsilon$, ubi variatio pro $\Delta \beta = 10''$ in eadem linea, & pro $\Delta \varepsilon$ in sequenti, quæ positivæ sunt, invenitur; ultima vero linea valorem $\text{Log}(1 - \varepsilon)$ tradit.

Ad inveniendas differentias sequentes adhiberi possunt formulæ, si hæ non ope tabularum trigonometricarum, quod minus exactum est, computentur.

$d\beta$ & $d\varepsilon$ in secundis exprimendæ.

$$d(\text{Log Cos } \beta \text{ Sin } \varepsilon) = -0,4343 \text{ Sin } 1'' \text{ tg } \beta d\beta + 0,4343 \text{ Sin } 1'' \text{ Cotg } \varepsilon d\varepsilon.$$

$$d(\text{Sin } \beta \text{ Cos } \varepsilon) = \text{Cos } \varepsilon \text{ Cos } \beta \text{ Sin } 1'' d\beta - \text{Sin } \beta \text{ Sin } \varepsilon \text{ Sin } 1'' d\varepsilon$$

$$d \text{Log} (\text{Cos } \beta \text{ Cos } \varepsilon) = -0,4343 \text{ Sin } 1'' \text{ tg } \beta d\beta - 0,4343 \text{ Sin } 1'' \text{ tg } \varepsilon d\varepsilon$$

$$d(\text{Sin } \beta \text{ Sin } \varepsilon) = \text{Cos } \beta \text{ Sin } \varepsilon \text{ Sin } 1'' d\beta + \text{Sin } \beta \text{ Cos } \varepsilon \text{ Sin } 1'' d\varepsilon$$

Si $d\beta = d\varepsilon = 10''$ erit in casu nostro approximatorie, hæc quatuor differentias per $d(1)$, $d(2)$ &c. designando

$$d(1) = -N \text{ tg } \beta + 0,00004850 (\text{Log } N = 5,32335)$$

$$d(2) = A \text{ Cos } \beta - B \text{ Sin } \beta (\text{Log } A = 5,64808; \text{Log } B = 5,28568).$$

$$d(3) = -N \text{ tg } \beta - 0,00000914$$

$$d(4) = B \text{ Cos } \beta + A \text{ Sin } \beta.$$

His jam argumentis facti, hyperque persuasione finemque prom-
issis mei jam facturo reliquum est, ut Te Celesterrimo ^{Deo}
professor, fautor ^{omaximar, quare distinguit, regem} & estimati ^{ob} benevolentiam et
humanitatem non hac occasione solum mihi ex-
hibeam, sed etiam per omnia id tempus, quo mihi
Te aut ^{partem} Academiae, Secretariae, aut ^{partem} Membra Se-
natus, Academici aut ^{partem} denique Decans Amplissimi
mi Ordinis philosophici semper facili et benigno
ubi trunque licuit. ^{illamque favorem} Te quomodo non nisi gratia mente
volisque lacilis remunerari possim, tamen laeta selector
sue, ^{isid, dubilo} ~~fore ut eandem mihi etiam in posterum bene-~~
~~volentiam et favorem sis conservaturus.~~ ^{expulere, sperare.}

Clarissime ^{Deo} Candide, Amico dilectis-
sime honoratissime!

Talem cum hac occasione te praeberis, qua
tam te equi & probe iudicii affirmatores antea cog-
noverunt, ~~etiam~~ nempe, de quo non modo bene
sperare, sed cui etiam confidere possent Cives sui in-
genere pro capite vero in hac litterarum fove, non
prosum non animulus Tibi gratulari, duo hoc op-
tans, quod utrumque te profuturum haud despero, ut
hauria qua propudiam ab ^{unum} ipso Urania sacerdote cin-
genda sunt tempora tua, nunquam ^{nunquam} virentem desierint,
alteram ut me ^{inter} innumeros amicos suos lucem ^{semper}
habeat. cum annuere.
